Imagine a new breed of nourishing crops capable of alleviating undernutrition in even the hardest-to-reach populations—crops such as rice with more iron, wheat packed with zinc, and maize strengthened with vitamin A. These staples could be grown on family farms throughout the developing world.
A Hidden Hunger

More than 840 million people do not have adequate food to meet their basic daily energy needs. Far more—an estimated three billion—suffer the insidious effects of micronutrient deficiencies because they lack money to buy enough meat, poultry, fish, fruits, legumes, and vegetables.

Women and children in Sub-Saharan Africa, South and Southeast Asia, and Latin America and the Caribbean are especially at risk for disease, premature death, and impaired cognitive abilities because of diets lacking essential micronutrients—particularly iron, vitamin A, iodine, and zinc.

Current efforts to combat micronutrient malnutrition in the developing world focus on providing vitamin and mineral supplements for pregnant women and young children and on fortifying foods with these nutrients through postharvest processing. These approaches have accomplished much. In regions with adequate infrastructure and well-established markets for delivering processed foods such as salt, sugar, and cereal flours, food fortification can greatly improve the micronutrient intake of vulnerable populations.

But there are limits to commercial fortification and supplementation. Fortified foods may not reach a large number of the people most in need because of weak market infrastructures. Supplementation likewise depends on a highly functional health infrastructure, a condition that is often absent in developing countries. Thus, new approaches are needed to complement existing interventions.

Biofortification

A New Paradigm for Agriculture and a Tool for Improving Human Health

The introduction of biofortified crops—varieties bred for increased mineral and vitamin content—will complement existing nutrition interventions and provide a sustainable and low-cost way of reaching people with poor access to formal markets or health care systems. Once the investment is made in developing nutritionally improved varieties at central research locations, seeds can be adapted to growing conditions in numerous countries. Biofortified varieties have the potential to provide ongoing benefits year after year throughout the developing world at a lower recurring cost than either supplementation or postproduction fortification.

The biofortification approach is backed by sound science. Research originally funded by the Danish International Development Assistance (Danida) and coordinated by the International Food Policy Research Institute (IFPRI) examined the feasibility of a plant breeding approach for improving the micronutrient content of staple crops. This research determined that:

- substantial, useful genetic variation in nutrient content exists in key staple crops;
- breeding programs can readily manage nutritional quality traits, which for some crops are highly heritable and simple to screen for;
- desired traits are sufficiently stable across a wide range of growing environments; and
- traits for high nutrient content can be combined with superior agronomic characteristics and high yields.
Winning Acceptance of Biofortified Crops

The crops included in the HarvestPlus program are already widely produced and consumed by poor households in the developing world but farmers need to be convinced to grow biofortified varieties and consumers must be persuaded to add them to their diets. The need for maintaining superior agronomic traits is paramount with biofortified varieties. Where scientists can combine high micronutrient content with high yield, farmer adoption and market success of nutritionally improved varieties is virtually guaranteed. Research has shown that high levels of minerals in seeds can also aid plant nutrition and thus improve yield. HarvestPlus employs participatory plant breeding techniques, in which scientists take farmers’ perspectives and preferences into account during the breeding process. This approach aids in the adoption of new crop varieties.

Convincing the undernourished to consume biofortified staples is by far the biggest challenge facing HarvestPlus. Improved mineral content, which generally does not alter appearance, taste, texture or cooking quality, is far less complicated than improving provitamin A content that may alter the color of food. HarvestPlus is working with health communication and behavior change specialists to ensure that creating demand for nutritious biofortified crops takes into account positive and negative consumer perceptions about the food they eat.

Distributing the New Varieties

A common problem in many developing countries is the lack of delivery systems to get products—be they from health or agronomic inputs—to the poorest people. HarvestPlus is overcoming this problem by implementing an end user strategy that identifies and addresses constraints to seed and extension systems, overcomes market impediments, and recognizes that substantive behavior change and health communication activities must accompany the development of the biofortified varieties.

Through their ongoing work with seed systems and their contributions to disaster-response, CGIAR centers have gained valuable experience in building and promoting local seed-distribution systems. These established systems offer a natural route for disseminating biofortified seed. HarvestPlus is drawing on the expertise of leading universities and civil society to analyze marketing systems and implement strategies to create demand for nutrient-dense crops. Local and regional agricultural committees and small-farmer seed enterprises, in particular, will play a crucial role in getting micronutrient-rich varieties into the hands of growers. Local marketing organizations and health communication specialists will help HarvestPlus effectively reach vulnerable undernourished children and their mothers.

Biofortification Makes Sense

The ultimate solution to eradicating undernutrition among the poor in developing countries is to diversify diets and substantially increase the consumption of nutrient-dense food such as meat, poultry, fish, fruits, legumes, and vegetables but it may take many decades for diversified diets to be affordable for the poor. Meanwhile, biofortification makes sense as part of an integrated food-systems approach to reducing undernutrition. It addresses the root causes of micronutrient malnutrition, targets the poorest people, uses built-in delivery mechanisms, is scientifically feasible and cost-effective, and complements other ongoing interventions to control micronutrient deficiencies. It is an essential first step in enabling rural households to improve family nutrition and health in a sustainable way.

HarvestPlus is a global alliance of research institutions and implementing agencies that have come together to breed and disseminate crops for better nutrition. It is coordinated by the International Center for Tropical Agriculture (CIAT) and the International Food Policy Research Institute (IFPRI). HarvestPlus is an initiative of the Consultative Group on International Agricultural Research (CGIAR).
The International Center for Tropical Agriculture (CIAT) and IFPRI are coordinating the plant breeding, human nutrition, crop dissemination, policy analysis, and impact activities that will be carried out at international agricultural research centers, national agricultural research and extension institutions, and departments of plant science and human nutrition at universities in both developing and developed countries. Nongovernmental organizations (NGOs) in developed and developing countries, farmer organizations, and public-private sector partnerships will strengthen the alliance and provide linkages to consumers. Initial biofortification efforts will focus on six staple crops for which prebreeding feasibility studies have been completed: beans, cassava, maize, rice, sweet potatoes, and wheat. The program will also examine the potential for nutrient enhancement in 10 additional crops that are important components in the diets of those with micronutrient deficiencies: bananas/plantains, barley, cowpeas, groundnuts, lentils, millet, pigeon peas, potatoes, sorghum, and yams.

**Objectives:**

### Years

#### 1 to 4

- Determine nutritionally optimal breeding objectives.
- Screen CGIAR germ plasm for high iron, zinc, and beta-carotene levels. Initiate crosses of high-yielding adapted germplasm for selected crops.
- Document cultural and food-processing practices, and determine their effect on micronutrient content and bioavailability.
- Discern the genetics of high micronutrient levels, and identify the markers available to facilitate the transfer of traits through conventional and novel breeding strategies.

#### 5 to 7

- Continue bioefficacy studies.
- Initiate participatory plant breeding.
- Adapt high-yielding, conventionally bred, micronutrient-dense lines to select regions.
- Release new conventionally bred biofortified varieties to farmers.
- Identify gene systems with potential for increasing nutritional value beyond traditional breeding methods.

#### 8 to 10

- Scale up the production and distribution of the improved varieties.
- Determine the nutritional effectiveness of the program, and identify factors affecting the adoption of biofortified crops, the impact on household resources, and the health effects on individuals.

### An International Consortium of Collaborative Partners

**Collaborating CGIAR Research Centers:** International Center for Tropical Agriculture (CIAT), International Maize and Wheat Improvement Center (CIMMYT), International Potato Center (CIP), International Center for Agricultural Research in the Dry Areas (ICARDA), International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), International Food Policy Research Institute (IFPRI), International Institute of Tropical Agriculture (IITA), International Rice Research Institute (IRRI), Africa Rice Center (WARDA), International Plant Genetic Resources Institute/International Network for the Improvement of Banana and Plantain (IPGRI/INIBAP).

**Partner Collaborating Institutions:** National agricultural research and extension systems (NARES) in developing countries, National Health Research and Implementation Systems (NHRIS), Departments of human nutrition and agriculture at universities in developing and developed countries; NGOs.

**Program Generously Supported By:** The Bill and Melinda Gates Foundation, Department for International Development, U.K. (DFID), Danish International Development Assistance (DANIDA), Swedish International Development Assistance (SIDA), the U.S. Agency for International Development (USAID), and the World Bank.
